How Common is Common Enough?

Finding Common Ground

...A story about a challenging situation* not dissimilar to others at a particular company.

“Common enough?”

How dissimilar is it to others?

Is it enough like what I experience in my own industry or research?

Are there ways in which I might appropriate what is common to my own experience?
Why even ask the question?

*Hypothetical program – “Codename: Blue”.*

Blue includes silicon, firmware, and application-level software. Some parts of Blue are developed jointly with a team from a subsidiary company. Blue is subject to many regulatory requirements, and also must comply with various standards and protocols. The team is globally-distributed, with program management, architecture, silicon development, software development, testing, sales, and support across many different sites.

“How common is common enough?”
Definitions: “Common” and “Enough”

**Common**  (ˈkämən)

- (adj) occurring, found or done often, prevalent
- Synonyms: usual, ordinary, familiar, regular, frequent, recurrent, everyday

“There teams used a **common** dictionary to define terms used in the specification.”

**Enough**  (iˈnəf)

- (det) as much or as many as **required**
- (adv) to the **required** degree or extent (after an adjective, adverb, or verb)

“**Enough** participants joined the user acceptance testing to confirm that the interface met usability targets.”

*Both commonality and sufficiency (“enoughness”)*
“Common Enough” practice – between two extremes

The commonality of any practice among adopting teams exists along a spectrum, with two relatively well-defined endpoints.

Uniformity
(Homogeneity)

Diversity
(Heterogeneity)

“Well-defined” does not automatically mean “often-occurring.” How many projects precisely follow the script of their methods or best practices? Are any projects subject to complete diversity, with no common practice, terminology, or process at all?
A range exists for each project or program.

Taken on their own, a specific set of homogenous practices implemented uniformly will generally entail little risk.

(Assuming, of course, that they are the right practices, and for some subset of programs.)
“Common Enough” – balancing investment and risk

A range exists for each project or program

Too much investment in driving commonality may increase, rather than decrease risk. Heterogeneous practice across different groups may be most effective, if local optimization can be bridged where necessary.
“Common Enough” – balancing diversity and investment

Range of satisficing – may be greater or lesser, depending on acceptable level of risk.

“Just enough” investment and common practice provides a satisfactory range of “enoughness” that allows work to move forward at an acceptable level of risk.

Requirements engineering

1. Gather raw requirements, including sources, all stakeholders, and rationale
2. Specify top-level requirements and ensuring requirements are complete, consistent, and feasible
3. Assessing, validating, and ensuring requirements and ensuring stakeholders requirements and accuracy of the requirements
4. Select design ideas and produce an Evolutionary Delivery plan
5. Manage Evolutionary Delivery project

Many, many tools...

Elicitation planning, Specification Quality Control, Panguage, Formal Specification, QFD, peer reviews, prototyping, ethnography, etc.
The framework organizes methodologies (and subsequent work) in a useful way.

Information at this level establishes the taxonomy and terminology used to communicate amongst team members as well as across group boundaries.

Too much commonality: Driving absolute consistency at all levels, in all ways, may lose important domain or disciplinary nuance, stifle innovation, and also be unnecessary effort.

Not enough commonality: Silos, with each group adopting (or inventing) a locally-optimized solution with little attempt to communicate across boundaries.
Methodologies

Methodologies prescribe activities that enable the agent or actor to fulfill the objectives of the methodology.

Too much commonality: Methods are identified as standards for all work, regardless of the nature of the work, the team, or other characteristics of the project at hand.

Not enough commonality: Every project begins anew, with no retrospective look at what worked before, and whether it might (or might not) work for the particular project.
Activities

Activities enable the agent or actor to fulfil the objectives of the methodology. As a discipline, RE has a set of activities that define a set of practices within them.

Too Much Commonality: We have to elicit “all the requirements” before we can begin any design or development.

Not Enough Commonality: No assessment of the activities to determine how and when they will take place.

Practices

Practices enable activities, and comprise the *applied* skills and techniques brought to bear on a particular project or program in order to achieve a particular end.

RE practices are the actions we employ in order to fulfill the activities. Each activity contains several possible practices – which will we choose for the project we are working on now?

**Too Much Commonality:** This practice worked well before, so it’ll work again, and always, on all projects.

**Not Enough Commonality:** Each team member chooses how she will do her work
Processes

Processes constrain the practices with specific tasks that define roles, responsibilities, and often the format and cadence of specific output.

Too much commonality: A single process description exists, and policies mandate that it be applied to all projects and programs, without appropriate tailoring

Not enough commonality: Process descriptions do not exist, or are written but widely disregarded. “Send me any feedback by Friday at 5.”
Many, many tools…

Tools & Data

**Tools and Data** - the repositories for and output of the processes, respectively.

Questions of commonality often arise about **tools**. Must an organization settle on “one tool to rule them all,” or is a heterogenous tool environment acceptable?

Questions about the commonality of **data** are often resolved through use of specific syntax.
Boundary issues

“Common enough” invokes the many memberships that are often silently at work in product development.

Boundaries between: Organizations, groups, individuals, disciplines, phases, methodologies, conceptual models, data sets, activities, languages, and many others.

What is common within a category may not be common when one crosses across a boundary into a different category.

“Does this word mean the same thing to me as it does to you?”

We need to find ways to work across all these boundaries
Protocols – working across boundaries

One very good way to work across boundaries is through use of protocols

- “code of correct conduct”, or “how unrelated objects communicate with each other”
- Protocols can be relatively simple, yet work in very complex settings (e.g., TCP/IP)

Example: Think about how commitments are made and viewed on an agile vs. traditional team

How do things change if we view commitment as a negotiated, cross-boundary communication device rather than a strict contract for enforcement?
Boundaries

Our discipline and the areas in which we work, as well as the ways we work themselves, are subject to ever more complexity.

The emphasis on increasingly complex systems emphasizing cross-cutting concerns results in factors that are very different from those such as weight or reliability.

• Where is user experience located?

• It is easy to find the battery in a system, but where is battery life found within the system?

More complexity often leads to demands for more commonality.
Two Threats to Finding “Common Enough”

Dogma
• (n) Dogma is a principle or set of principles laid down by an authority as incontrovertibly true. It serves as part of the primary basis of an ideology, nationalism or belief system, and it cannot be changed or discarded without affecting the very system's paradigm, or the ideology itself.

Corruption
• (n) In philosophical, theological, or moral discussions, corruption is spiritual or moral impurity or deviation from an ideal. [...] The word corrupt when used as an adjective literally means “utterly broken.”

Dogma and corruption are not necessarily opposite concepts. Might dogmatic application of a particular method or practice result in a project that is “utterly broken?”

Challenge: find the spot that is “common enough” – and have the courage to change it as needed. Complex adaptive systems demand it.
The Role of RE in a Complex World

How might we define “common enough” RE for Codename: Blue?

**Framework:** Acknowledge that different segments of the project will work differently. Establish glossary, name boundaries.

**Activities:** Each part of the program agrees on the model of 5 RE activities.

**Practices:** Actual means of implementing the activities may differ (Scrum for SW dev, inspections for hardware architecture specs, etc.)

**Tools:** VERY heterogenous environment. Common language.

Is It Common Enough? Some closing thoughts.

No bright line rule for “common enough.” (Sorry.)

- Requirements statements will likely never reach the point where “too common” is an issue.
- Requirements can be “not common enough” – insufficient commonality is a sign of false consensus, especially in a very heterogeneous environment.
- Imposed commonality on methods may lead to very poor results in innovation, with deleterious effects in a complex environment.

No upper limits to creativity! (Usually...)

- Know the many boundaries your program must traverse, and ensure that protocols are in place to communicate across them.
- Within any given group, innovation and creative means of sensing and responding to complexity can yield good results.
Finally

“All models are wrong, but some of them are useful.” George Box

Finding **common enough** requires fluency in a wide range of “wrong but useful models.”

Conferences such as REFSQ are excellent opportunities to explore more models, and ask the question of whether another’s experience or idea just might be common enough to work in a situation in your own environment.

Many thanks for the opportunity to ask and discuss the question, “How common is common enough?”

Not just for Requirements anymore: The “3 Cs”

Requirements help establish a clear, common, and coherent understanding of what the system must accomplish.

**Clear**: All statements are unambiguous, complete, and concise

**Common**: All stakeholders share the same understanding

**Coherent**: All statements are consistent and form a logical whole

*Clarity* can be judged through evaluating a statement for ambiguity, assessing its completeness for its intended purpose, and determining the absence of extraneous content.

*Coherence* refers to the conceptual integrity of the group of statements as a whole.

*Commonality* of understanding of requirements statements is simple, but a more complex question arises with questions of stakeholder definition and project management.
Intel Emergent Systems and Coaching

RE at Intel has been housed in several parts of the company over nearly 15 years.

- Quality
- Project Controls / Project Management
- Software Program Office
- Emergent Systems (since Dec 2012)

“Emergent Systems”

- Not about providing a packaged method, but about adding value and facilitating transformation.
- Agile, RE, Change Agency, Technical Practices (Test-Driven Development), Lean, complex systems research, etc. in a small group of senior practitioners and thought leaders
- Different perspective on the work, as we’re not about teaching techniques as much as we are about organizational transformation.
